

### (iii) Nested Loop

A nested loop is a loop within a loop.

The inner loop will iterate through its entire cycle for each iteration of the outer loop.

- For loop inside for loop
- For loop inside while loop.
- while loop inside for loop
- while loop inside while loop.

\* For loop inside for loop

System: for Variable (1) in range (1, 11, 1): # outer loop.

for Variable 2 in range (1): inner loop.

Statement of inner loop.

Statement of outer loop.

Eg: multiplication table from 1 to 10.

for i in range (1, 11, 1):

for j in range (1, 11, 1):

print (i\*j, end=" ")

print()

\* ~~for~~ while loop inside while loop

System:

Initialization of outer loop.

while Condition: outer loop.

Initialization of inner loop.

while Condition: inner loop.

Statements of inner loop.

inc/dec of inner loop

Statements of ~~outer~~ loop.

inc/dec of ~~outer~~ loop.

Example: multiplication table from 1 to 10.

i = 1

while i <= 10:

j = 1

while j <= 10:

print (i\*j, end=" ")

j = j + 1

print()

i = i + 1

\* while inside a for loop ( " " ) loop

For variable in range ( ) : outer loop

For variable in range(): outer loop

initialization.

while (condition): inner loop.

Statement of inner loop.

inc/dec of while loop

Statement of outer loop is used as it contains 4

Example

for  $i$  in range(1, 6, 1):

$$J = 1$$

```
while (j <= 15):
```

```
print(" ", end=" ").
```

$$j = j + 1$$

```
print (i, end=" ")
```

$k_2 i$

$$y = 1$$

while  $y \neq z$ .

$\text{Prnt}(k, \text{encl} = " ")$

 $y = y + 1$ 

```
print()
```

\* For ~~while~~ inside a ~~for~~ while loop

### Initialization of while loop

while (condition): Outer loop.

for variable in range(6)

### Statement of inner loop.

Statement of outer loop.

inc / dec of while loop.

Example

921

while ( $i < 5$ ):

for  $k$  in range  $(1, G, 1)$ :

```

print("*", end=" ")
else:
    print(" ", end=" ")

```

```

print()
p = p + 1

```

## \* FUNCTIONS

A function is a block of code that performs a specific task.

Function make our program more (organized), readable, and reduce repetition.

→ Types:

### ① Built in function:

It is already available in Python.

type(), print(), input(), len().

### ② user defined function:

Functions are created by user using def (define) keyword.

```
def function_name (parameter):
```

Statement

return value.

[Return instead of print]

(i) Function without input & without return.

(ii) Function with input & without return.

(iii) Function without input and with return.

(iv) Function with input & with return.

### ③ Lambda function

Anonymous (Nameless) functions written in single line using the lambda keyword.

# 1. Function without input and without return

```
def fun_name():
```

Statements.

Call the function.

function-name.

Variable inside a function is called local variable.  
It can't be used outside the function.

example: Addition of 2 numbers.

```
def add1():
```

```
x = int(input("enter a value"))
```

```
y = int(input("enter a value"))
```

```
s = x + y
```

```
print("Sum of {x} and {y} is {s}")
```

Call the function.

```
add1()
```

Output: Enter a value: 3

Enter a value: 4

Sum of 3 & 4 is 7.

# 2. Function with input and without return

```
def fun_name(p1, p2, ... pn):
```

Statements.

(Call the function)

fun-name.

example (Addition)

```
def add2(x, y):
```

```
s = x + y
```

```
Print("The sum of {x} and {y} is {s}")
```

```
add2(4, 5)
```

Output: Sum of 4 and 5 is 9

### 3. Function without input and with return

```
def fun_name():  
    Statement  
    return value
```

example:

```
def add3():
```

```
    x = int(input("enter x value"))
```

```
    y = int(input("enter y value"))
```

```
    s = x + y
```

```
    return x, y, s
```

```
add3()
```

```
enter x value = 3
```

```
enter y value = 4
```

```
Sum = add3()
```

### 4. Function with input and with return

```
def fun_name(P1, P2... Pn):
```

```
    Statements
```

```
    return value
```

example:

```
def add4(x, y):
```

```
    s = x + y
```

```
    return x, y, s
```

```
add4(2, 3)
```

Output:

```
(2, 3, 5)
```

```
x, y, s = add4(2, 3)
```

Print ("Sum of {x} and {y} is {s}")  
Sum of 2 and 3 is 5

### Example

Create a function to check the given number is prime or not using with input and without return method.

```
def prime(n):
```

```
    for p in range(2, n, 1):
```

```
        if (n % p == 0):
```

```
            print(n, " is not prime number")
```

```
            break.
```

```
    else:
```

```
        print(n, " is prime number")
```

```
prime(19)
```

Output:

19 is prime number.
